Jean BONCOEUR

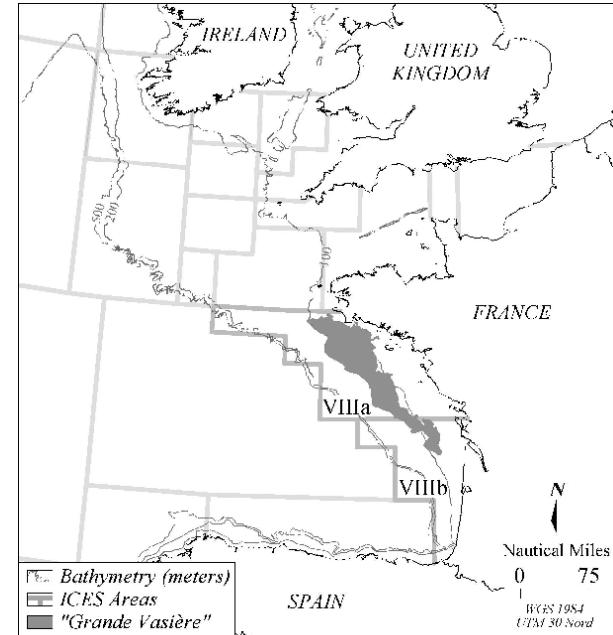

Plan of the presentation

1. Context
2. Bio-economic modelling and social cost
3. Results of the estimation of social cost
4. Discussion

1. Context

Nephrops trawl fishery:

- ~ 250 trawlers
- ~ 3800 tonnes of *Nephrops* per year (30 million euros)
- ~ 80 million euros total gross revenue

High levels of by-catches and discards of many species

- *Nephrops* discards = 60% of the *Nephrops* caught in number and 30% in weight [ICES, 2006] (*Nephrops* <9cm)
- Hake discards = 97% of the hake caught in number (hake <27cm)

Main reasons for discarding younger age groups :

Low selectivity of bottom trawlers combined with Minimum Landing Size (MLS)

High discards mortality rates → discarding practices = waste

- For the stocks that endure unprofitable fishing mortality
- For the fleets targeting or by-catching these species (gillnetters, trawlers and longliners)
- For the consumer through the price-quantity relationship
- For the state through the landing taxes

→ High social cost

Objective:

To estimate the social cost generated by the *Nephrops* trawler fleet through *Nephrops* and hake discards under the minimum landing size

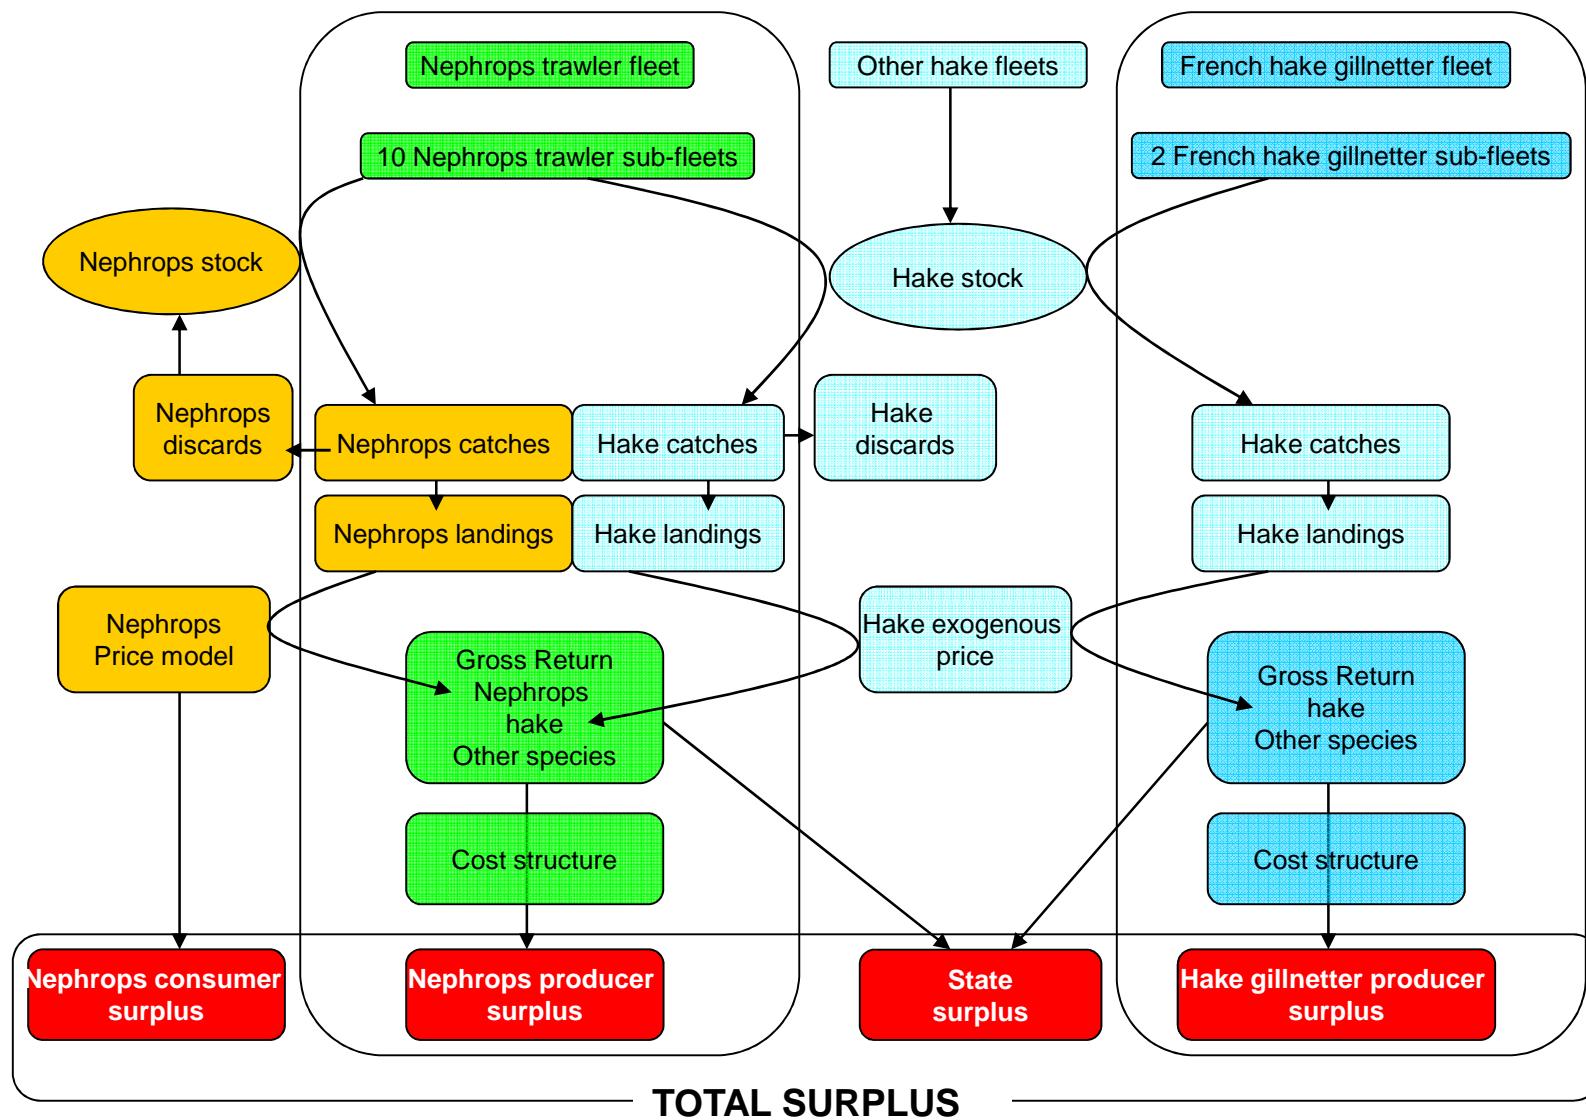

2. Bio-economic modelling and social cost

Social cost: Difference of net benefit between the status quo and the best technically feasible alternative (Coase, 1960)

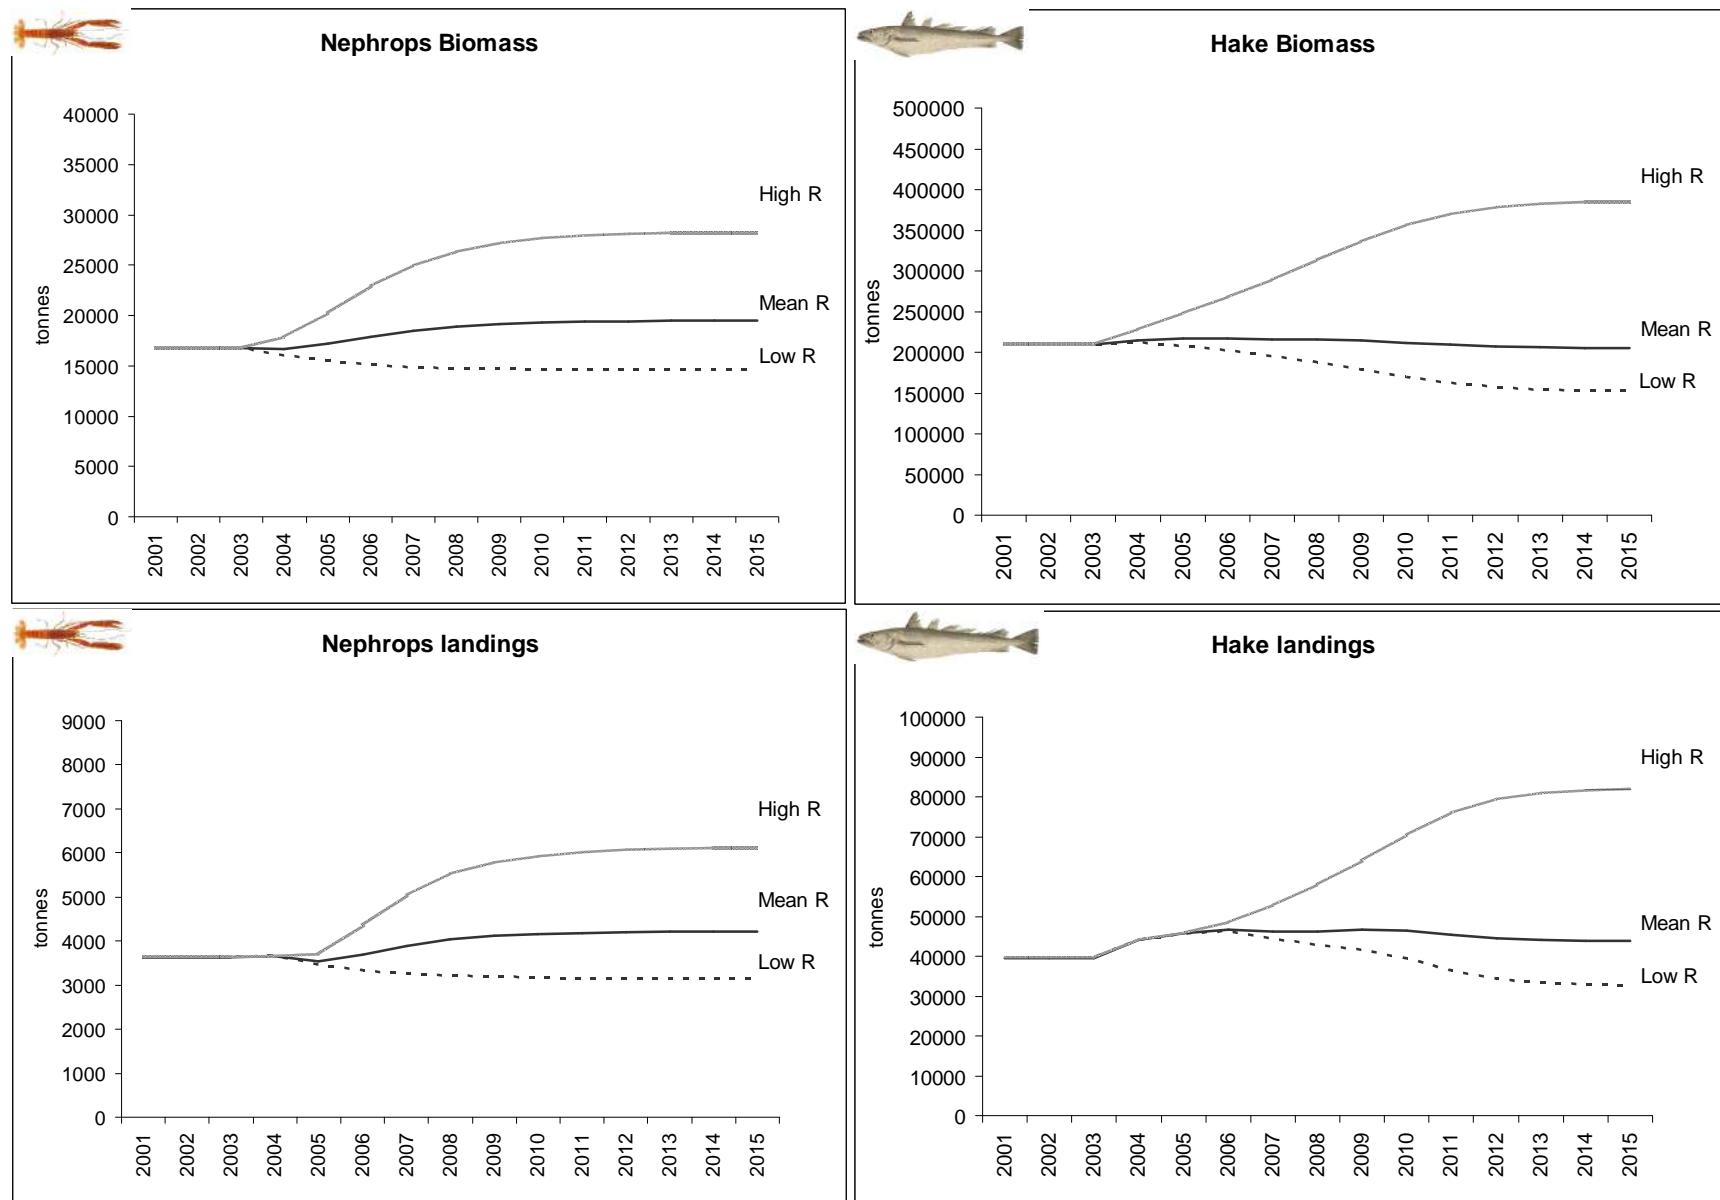

Scenario studied: a selective device such that there is no catch of :
Nephrops <MLS (age group <3)
Hake < MLS (age group <2)

Assumptions:

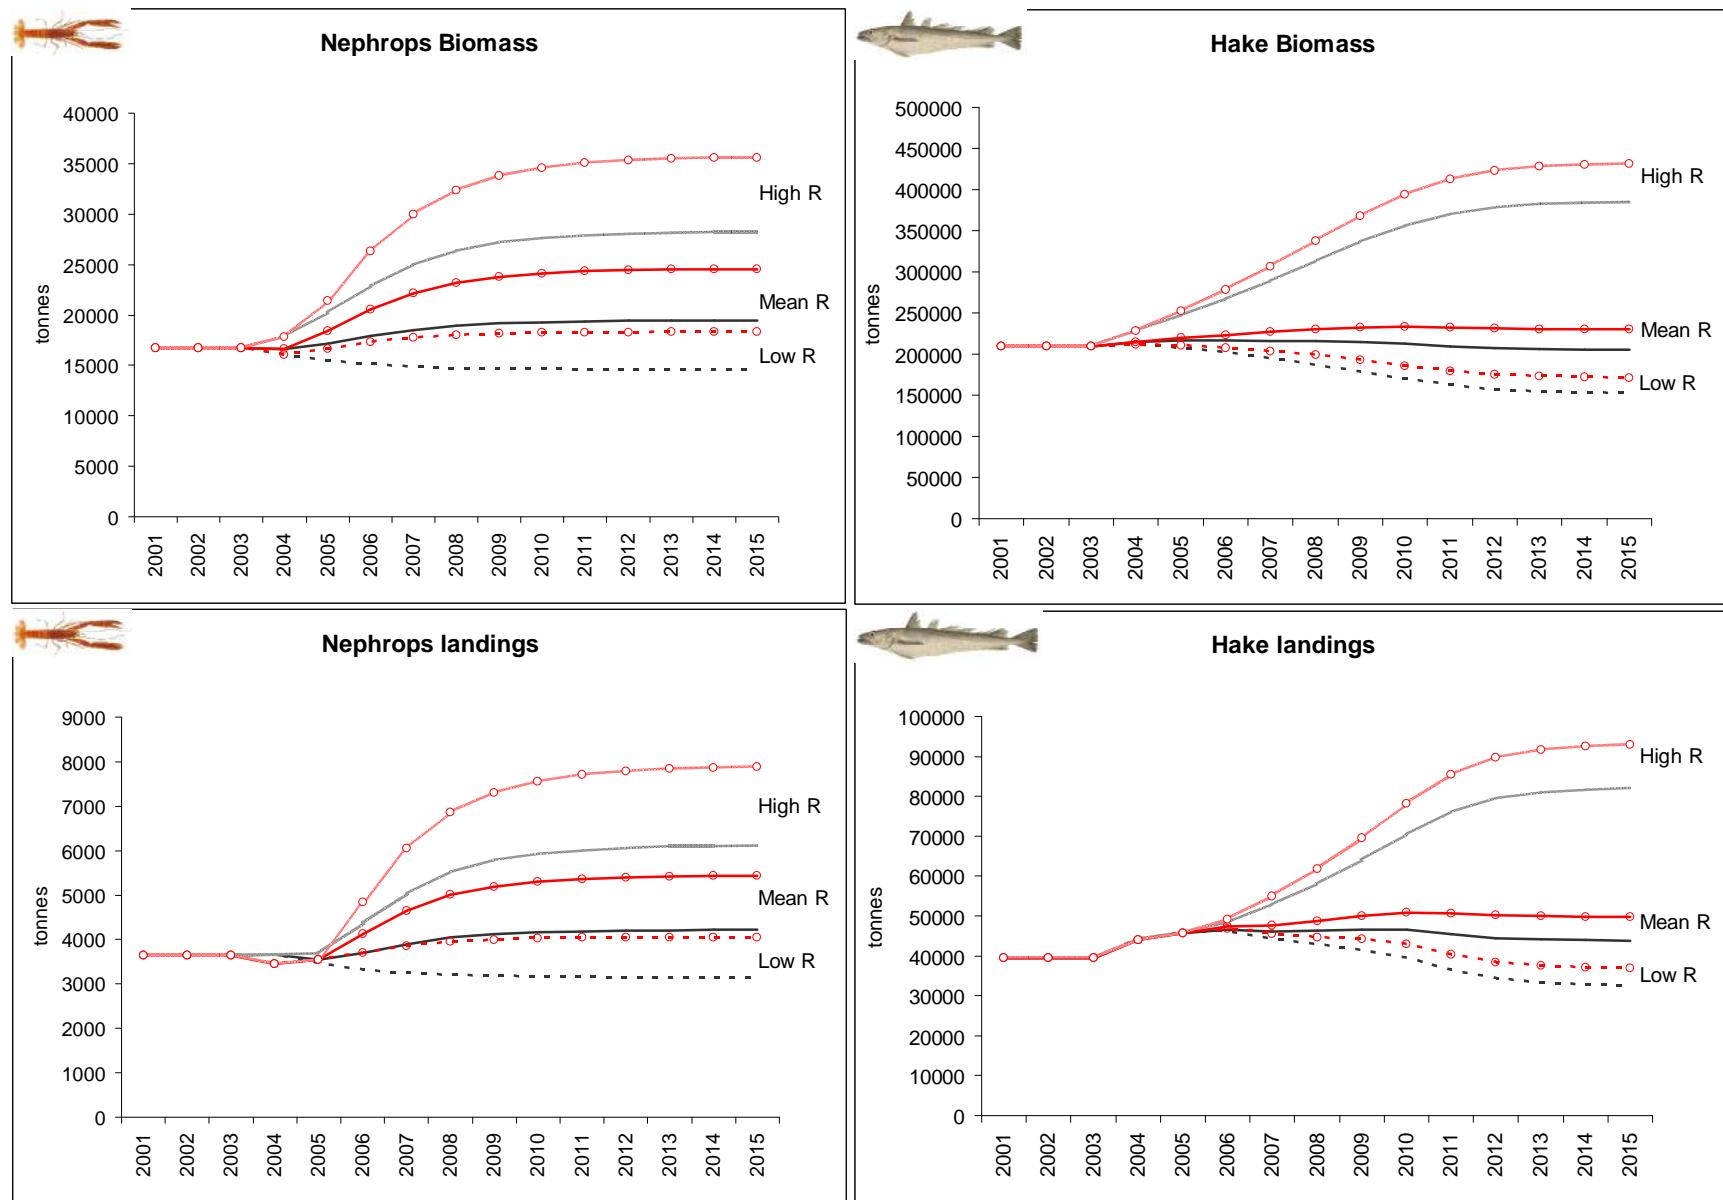

Multi-fleet, multi-metier, multi-species
constant effort
constant recruitment (Low and high assumptions tested)
3 Nephrops price models
exogeneous hake price

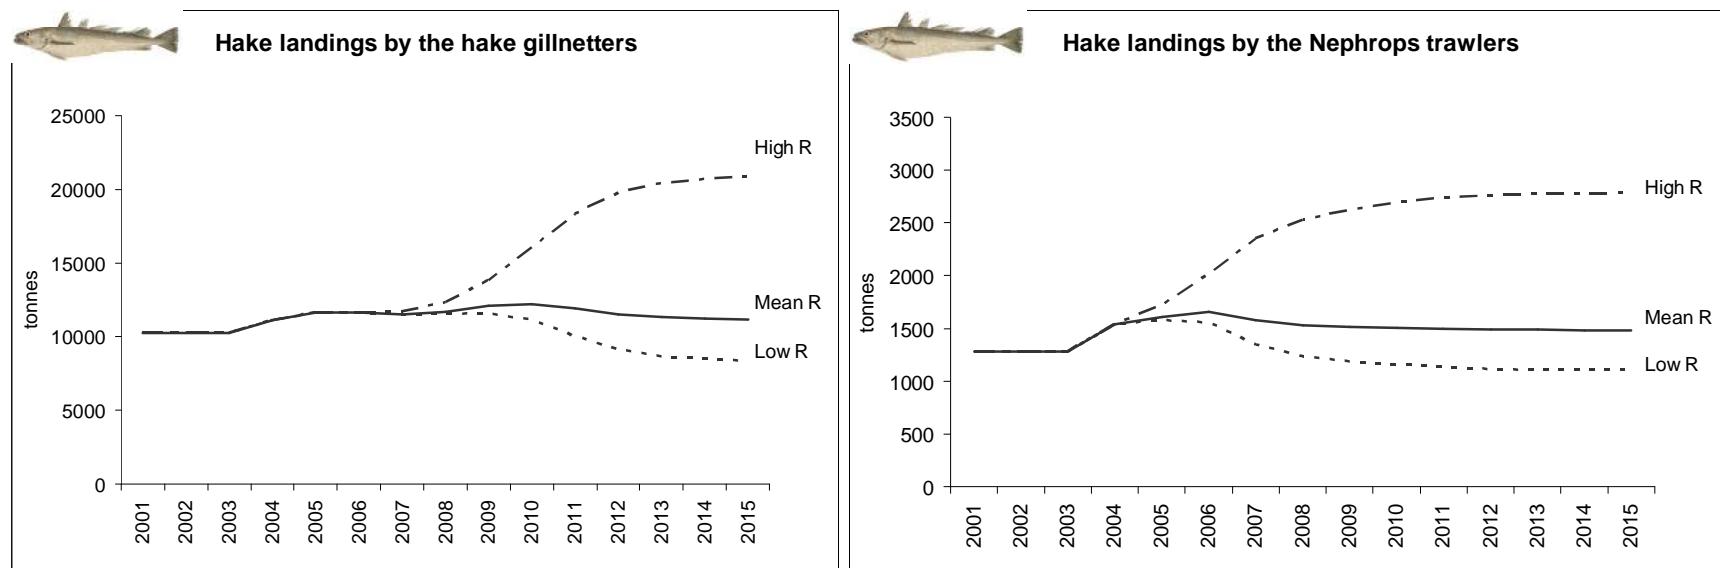

3. Results

Discards

Biomass and Landings

3. Results

→ Social cost ~ 50 keuros per Nephrops trawler per year (internal cost and external cost for consumers, state and other producers)

4. Discussion and perspectives

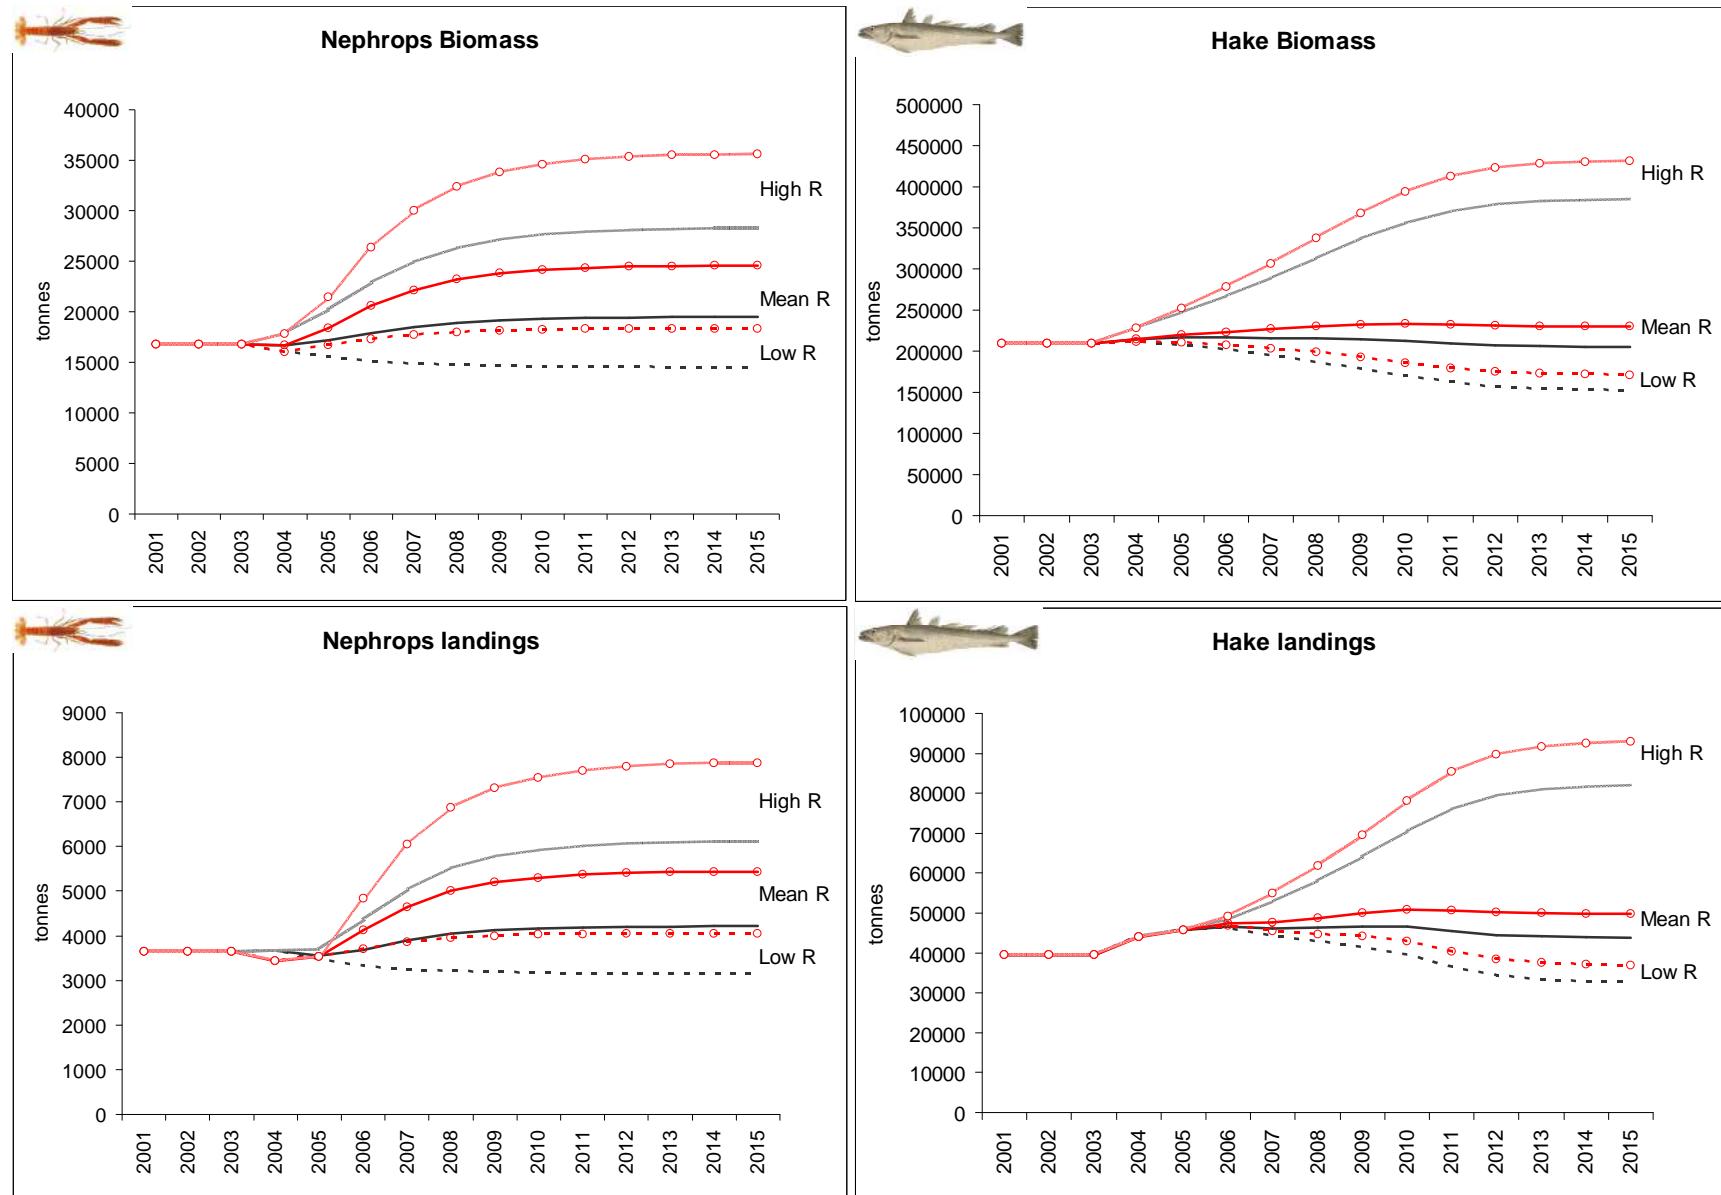

- Nephrops trawlers do not bear all their production costs
- Improving selectivity → social benefit for Nephrops producers, other producers, consumer and state
- Does not resolve the access regulation problem : taking account of investment dynamic through increasing catchability → rent drains
- Right based management difficult to implement in a mixed fishery
- → combine selectivity improvement and access regulation
- ! Selectivity improvement generally non observable+ strong incentives to circumvent selective improvement !

Perspectives of this work

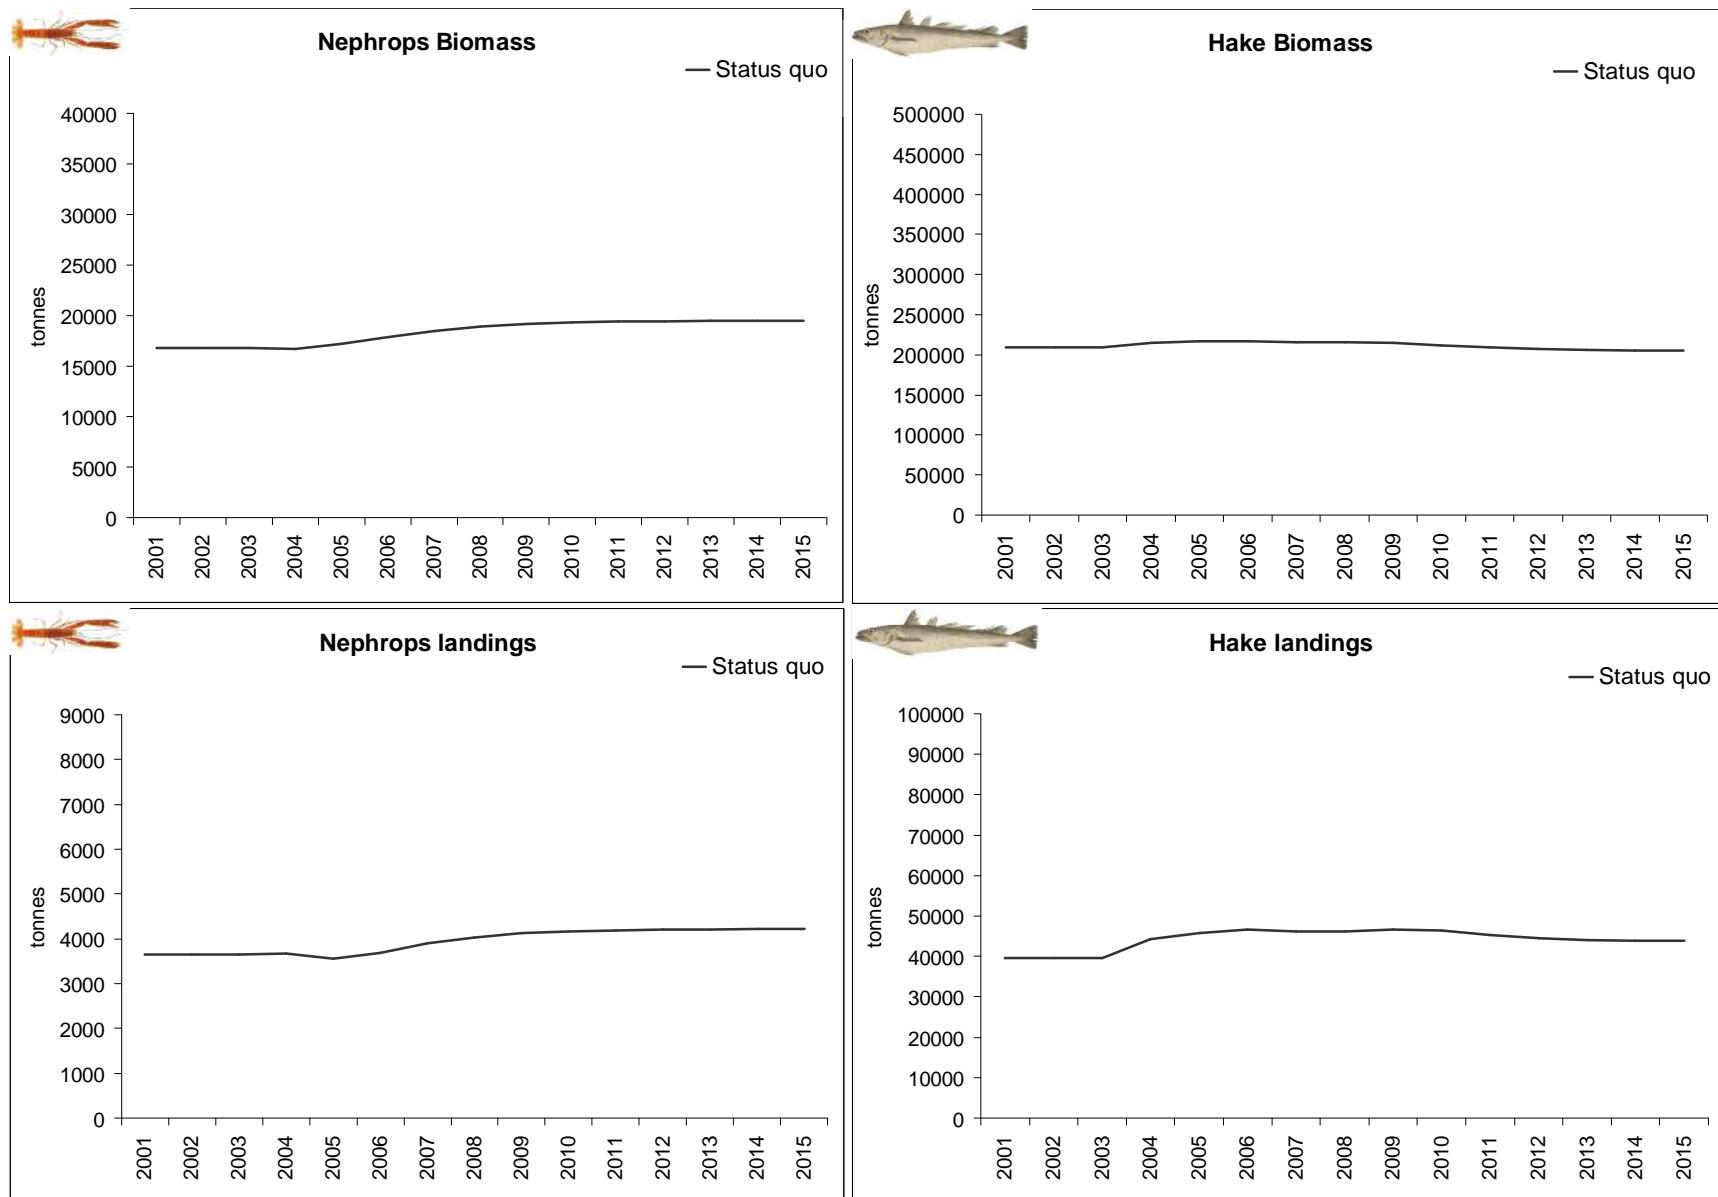

- uncertainties
- Other fleets and other commercial and non commercial species
- Market
- Microeconomic Behaviors

THANK YOU!
